## Package 'robustX'

June 16, 2023

Type Package

Title 'eXtra' / 'eXperimental' Functionality for Robust Statistics

Version 1.2-7

Date 2023-06-14

Maintainer Martin Maechler <maechler@stat.math.ethz.ch>

Description Robustness -- 'eXperimental', 'eXtraneous', or 'eXtraordinary' Functionality for Robust Statistics. Hence methods which are not well established, often related to methods in package 'robustbase'. Amazingly, 'BACON()', originally by Billor, Hadi, and Velleman (2000) <doi:10.1016/S0167-9473(99)00101-2> has become established in places. The ``barrow wheel'' `rbwheel()` is from Stahel and Mächler (2009) <doi:10.1111/j.1467-9868.2009.00706.x>.

**Imports** grDevices, graphics, stats, utils, robustbase (>= 0.92-3)

Suggests MASS, lattice, pcaPP

Enhances ICS

License GPL (>= 2)

**Encoding** UTF-8

NeedsCompilation no

robustX-package eXperimental eXtraneous ... Functionality for Robust Statistics

## Description

The package **robustX** aims to be a collection of R functionality for robust statistics of methods and ideas that are considered as proposals, experimental, for experiences or just too much specialized to be part of the "Robust Basics" package **robustbase**.

BACON

BACON for Regression or Multivariate Covariance Estimation

#### Description

BACON, short for 'Blocked Adaptive Computationally-Efficient Outlier Nominators', is a somewhat robust algorithm (set), with an implementation for regression or multivariate covariance estimation.

BACON() applies the multivariate (covariance estimation) algorithm, using mvBACON(x) in any case, and when y is not NULL adds a regression iteration phase, using the auxiliary .lmBACON() function.

#### Usage

```
BACON(x, y = NULL, intercept = TRUE,
    m = min(collect * p, n * 0.5),
    init.sel = c("Mahalanobis", "dUniMedian", "random", "manual", "V2"),
    man.sel, init.fraction = 0, collect = 4,
    alpha = 0.05, alphaLM = alpha, maxsteps = 100, verbose = TRUE)
## *Auxiliary* function:
.lmBACON(x, y, intercept = TRUE,
    init.dis, init.fraction = 0, collect = 4,
    alpha = 0.05, maxsteps = 100, verbose = TRUE)
```

#### Arguments

x	a multivariate matrix of dimension [n x p] considered as containing no missing values.
У	the response (n vector) in the case of regression, or NULL for the multivariate case, where just $mvBACON()$ is returned.
intercept	logical indicating if an intercept has to be used for the regression.
m	integer in 1:n specifying the size of the initial basic subset; used only when init.sel is not "manual"; see mvBACON.
init.sel	character string, specifying the initial selection mode; see mvBACON.
man.sel	<pre>only when init.sel == "manual", the indices of observations determining the initial basic subset (and m &lt;- length(man.sel)).</pre>
init.dis	the distances of the x matrix used for the initial subset determined by $mvBACON$ .
init.fraction	if this parameter is > 0 then the tedious steps of selecting the initial subset are skipped and an initial subset of size $n * init.fraction$ is chosen (with smallest dis)
collect	numeric factor chosen by the user to define the size of the initial subset (p $\ast$ collect)
alpha	number in $(0,1)$ determining the cutoff value for the Mahalanobis distances (multivariate outlier nomination in mvBACON()), or the discrepancies for regression, see alphaLM.
alphaLM	number in $(0,1)$ where a 1-alphaM t-quantile is the cutoff for the discrepancies (for regression, .lmBACON()); see details.
maxsteps	the maximal number of iteration steps (to prevent infinite loops)
verbose	logical indicating if messages are printed which trace progress of the algorithm.

## Details

Notably about the initial selection mode, init.sel, see its description in the mvBACON arguments list.

The choice of alpha and alphaLM:

- Multivariate outlier nomination: see the Details section of mvBACON.
- Regression: Let  $t_r(\alpha)$  denote the  $1 \alpha$  quantile of the Student *t*-distribution with *r* degrees of freedom, where *r* is the number of elements in the current subset; e.g.,  $t_r(0.05)$  is the 0.95 quantile. Following Billor et al. (2000), the cutoff value for the discrepancies is defined as  $t_r(\alpha/(2r+2))$ , and they use  $\alpha = 0.05$ . Note that this is argument alphaLM (defualting to alpha) for BACON().

## Value

BACON(x,y,..) (for regression) returns a list with components

subset the observation indices (in 1:n) denoting a subset of "good" supposedly outlierfree observations.

tis	the $t_i(y_m, X_m)$ of eq (6) in the reference; the clean "basic subset" in the algorithm is defined the observations <i>i</i> with the smallest $ t_i $ , and the $t_i$ can be regarded as scaled predicted errors.
mv.dis	the (final) discrepancies or distances of mvBACON().
mv.subset	the "good" subset from mvBACON(), used to start the regression iterations.

#### Note

"BACON" was also chosen in honor of Francis Bacon:

Whoever knows the ways of Nature will more easily notice her deviations; and, on the other hand, whoever knows her deviations will more accurately describe her ways. Francis Bacon (1620), Novum Organum II 29.

#### Author(s)

Ueli Oetliker, Swiss Federal Statistical Office, for S-plus 5.1; 25.05.2001; modified six times till 17.6.2001.

Port to R, testing etc, by Martin Maechler. Daniel Weeks (at pitt.edu) proposed a fix to a long standing buglet in GiveTis() computing the  $t_i$ , which was further improved Maechler, for **robustX** version 1.2-3 (Feb. 2019).

Correction of alpha default, from 0.95 to 0.05, by Tobias Schoch, see mvBACON.

#### Examples

require(robustbase)

```
(RlmST <- lmrob(log.light ~ log.Te, data = starsCYG))
abline(RlmST, col = "blue")</pre>
```

covNNC

Robust Covariance Estimation via Nearest Neighbor Cleaning

## Description

covNNC() estimates robust covariance/dispersion matrices by the nearest neighbor variance estimation (NNVE) or (rather) "Nearest Neighbor Cleaning" (NNC) method of Wang and Raftery (2002, *JASA*).

#### Usage

## Arguments

Х	matrix in which each row represents an observation or point and each column represents a variable.
k	desired number of nearest neighbors (default is 12)
pnoise	percent of added noise
emconv	convergence tolerance for EM
bound	value used to identify surges in variance caused by outliers wrongly included as signal points (bound = 1.5 means a 50 percent increase)
extension	whether or not to continue after reaching the last chi-square distance. The default is to continue, which is indicated by setting extension = TRUE.
devsm	when extension = TRUE, the algorithm stops if the relative difference in variance is less than devsm. (default is $0.01$ )

#### Value

A list with components

cov	covariance matrix
mu	mean vector
postprob	posterior probability
classification	classification (0=noise otherwise 1) obtained by rounding postprob
innc	list of initial nearest neighbor cleaning results (components are the covariance, mean, posterior probability and classification)

6

#### L1median

## Note

Terms of use: GPL version 2 or newer.

MM: Even though covNNC() is backed by a serious scientific publication, I cannot recommend its use at all.

#### Author(s)

Naisyin Wang <nwang@stat.tamu.edu> and Adrian Raftery <raftery@stat.washington.edu> with contributions from Chris Fraley <fraley@stat.washington.edu>.

covNNC(), then named cov.nnve(), used to be (the only function) in CRAN package **covRobust** (2003), which was archived in 2012.

Martin Maechler allowed ncol(X) == 1, sped up the original code, by reducing the amount of scaling; further, the accuracy was increased (using internal q.dDk()). The original version is available, unexported as robustX:::covNNC1.

#### References

Wang, N. and Raftery, A. (2002) Nearest neighbor variance estimation (NNVE): Robust covariance estimation via nearest neighbor cleaning (with discussion). *Journal of the American Statistical Association* **97**, 994–1019.

See also University of Washington Statistics Technical Report 368 (2000); see at https://stat.uw.edu/research/tech-reports/

#### See Also

cov.mcd from package MASS; covMcd, and covOGK from package robustbase.

The whole package **rrcov**.

#### Examples

```
data(iris)
covNNC(iris[-5])
```

```
data(hbk, package="robustbase")
hbk.x <- data.matrix(hbk[, 1:3])
covNNC(hbk.x)</pre>
```

L1median

Compute the Multivariate L1-Median aka 'Spatial Median'

#### Description

Compute the multivariate  $L_1$ -median m, also called "Spatial Median", i.e., the minimizer of

$$\sum_{i=1}^n \|x_i - m\|$$

where  $\|u\| = \sqrt{\sum_{j=1}^{p} u_j^2}$ .

As a convex problem, there's always a global minimizer, computable not by a closed formula but rather an iterative search. As the (partial) first derivatives of the objective function is undefined at the data points, the minimization is not entirely trivial.

## Usage

```
L1median(X, m.init = colMedians(X), weights = NULL,
method = c("nlm", "HoCrJo", "VardiZhang", optimMethods, nlminbMethods),
pscale = apply(abs(centr(X, m.init)), 2, mean, trim = 0.40),
tol = 1e-08, maxit = 200, trace = FALSE,
zero.tol = 1e-15, ...)
```

## Arguments

Х	numeric matrix of dimension $n \times p$ , say.
m.init	starting value for $m$ ; typically and by default the coordinatewise median.
weights	optional numeric vector of non-negative weights; currently only implemented for method "VardiZhang".
method	character string specifying the computational method, i.e., the algorithm to be used (can be abbreviated).
pscale	numeric p-vector of positive numbers, the coordinate-wise scale (typical size of $\delta m_j$ ), where m is the problem's solution.
tol	positive number specifying the (relative) convergence tolerance.
maxit	positive integer specifying the maximal number of iterations (before the itera- tions are stopped prematurely if necessary).
trace	an integer specifying the tracing level of the iterations; 0 does no tracing
zero.tol	for method "VardiZhang", a small positive number specifying the tolerance for determining that the iteration is 'exactly' at a data point (which is a singularity).
	optional arguments to nlm() or the control (list) arguments of optim(), or nlminb(), respectively.

## Details

Currently, we have to refer to the "References" below.

## Value

currently the result *depends* strongly on the method used. FIXME. This will change considerably.

#### mvBACON

#### Author(s)

Martin Maechler. Method "HoCrJo" is mostly based on Kristel Joossens' R function, implementing Hossjer and Croux (1995).

pm <- sapply(L1m, function(.) if(is.numeric(.)) . else .$par)
t(pm) # SANN differs a bit; same objective ?
```

BACON: Blocked Adaptive Computationally-Efficient Outlier Nominators

#### Description

This function performs an outlier identification algorithm to the data in the x array [n x p] and y vector [n] following the lines described by Hadi et al. for their BACON outlier procedure.

#### Arguments

х	numeric matrix (of dimension $[nxp]$ ), not supposed to contain missing values.
collect	a multiplication factor $c$ , when init.sel is not "manual", to define $m$ , the size of the initial basic subset, as $m := c \cdot p$ , in practice, m <- min(p * collect, n/2).
m	integer in 1:n specifying the <i>size</i> of the initial basic subset; used only when init.sel is not "manual".
alpha	determines the cutoff value for the Mahalanobis distances (see details).
init.sel	character string, specifying the initial selection mode; implemented modes are:
	" <b>Mahalanobis</b> " based on Mahalanobis distances (default); the version V1 of the reference; affine invariant but not robust.
	"dUniMedian" based on the distances from the univariate medians; similar to the version $V2$ of the reference; robust but not affine invariant.
	"random" based on a random selection, i.e., reproducible only via set.seed().
	"manual" based on manual selection; in this case, a vector man.sel containing the indices of the selected observations must be specified.
	"V2" based on the Euclidean norm from the <b>uni</b> variate medians; this is the version $V2$ of the reference; robust but not affine invariant.
	"Mahalanobis" and "V2" where proposed by Hadi and the other authors in the reference as versions 'V_1' and 'V_2', as well as "manual", while "random" is provided in order to study the behaviour of BACON. Option "dUniMedian" is similar to "V2" and is due to U. Oetliker.
man.sel	only when init.sel == "manual", the indices of observations determining the initial basic subset (and m <- length(man.sel)).
maxsteps	maximal number of iteration steps.
allowSingular	logical indicating a solution should be sought also when no matrix of rank $p$ is found.
verbose	logical indicating if messages are printed which trace progress of the algorithm.

#### Details

Remarks on the tuning parameter alpha: Let  $\chi_p^2$  be a chi-square distributed random variable with p degrees of freedom (p is the number of variables; n is the number of observations). Denote the  $(1 - \alpha)$  quantile by  $\chi_p^2(\alpha)$ , e.g.,  $\chi_p^2(0.05)$  is the 0.95 quantile. Following Billor et al. (2000), the cutoff value for the Mahalanobis distances is defined as  $\chi_p(\alpha/n)$  (the square root of  $chi_p^2$ ) times a correction factor c(n, p), n and p, and they use  $\alpha = 0.05$ .

#### mvBACON

#### Value

a list with components

subset	logical vector of length n where the i-th entry is true iff the i-th observation is part of the final selection.
dis	numeric vector of length n with the (Mahalanobis) distances.
cov	$p \times p$ matrix, the corresponding robust estimate of covariance.

#### Author(s)

Ueli Oetliker, Swiss Federal Statistical Office, for S-plus 5.1. Port to R, testing etc, by Martin Maechler; Init selection "V2" and correction of default alpha from 0.95 to 0.05, by Tobias Schoch, FHNW Olten, Switzerland.

#### References

Billor, N., Hadi, A. S., and Velleman, P. F. (2000). BACON: Blocked Adaptive Computationally-Efficient Outlier Nominators; *Computational Statistics and Data Analysis* **34**, 279–298. doi:10.1016/ S01679473(99)001012

#### See Also

covMcd for a high-breakdown (but more computer intensive) method; BACON for a "generalization", notably to *regression*.

#### Examples

```
require(robustbase) # for example data and covMcd():
## simple 2D example :
plot(starsCYG, main = "starsCYG data (n=47)")
B.st <- mvBACON(starsCYG)</pre>
points(starsCYG[ ! B.st$subset,], pch = 4, col = 2, cex = 1.5)
stopifnot(identical(which(!B.st$subset), c(7L,11L,20L,30L,34L)))
## finds the 4 clear outliers (and 1 "borderline");
## it does not find obs. 14 which is an outlier according to covMcd(.)
iniS <- setNames(, eval(formals(mvBACON)$init.sel)) # all initialization methods, incl "random"</pre>
set.seed(123)
Bs.st <- lapply(iniS[iniS != "manual"], function(s)</pre>
                mvBACON(as.matrix(starsCYG), init.sel = s, verbose=FALSE))
ii <- - match("steps", names(Bs.st[[1]]))</pre>
Bs.s1 <- lapply(Bs.st, `[`, ii)</pre>
stopifnot(exprs = {
   length(Bs.s1) >= 4
   length(unique(Bs.s1)) == 1 # all 4 methods give the same
})
## Example where "dUniMedian" and "V2" differ :
data(pulpfiber, package="robustbase")
dU.plp <- mvBACON(as.matrix(pulpfiber), init.sel = "dUniMedian")</pre>
V2.plp <- mvBACON(as.matrix(pulpfiber), init.sel = "V2")</pre>
```

```
(oU <- which(! dU.plp$subset))</pre>
(o2 <- which(! V2.plp$subset))</pre>
stopifnot(setdiff(o2, oU) %in% c(57L,58L,59L,62L))
## and 57, 58, 59, and 62 *are* outliers according to covMcd(.)
## 'coleman' from pkg 'robustbase'
coleman.x <- data.matrix(coleman[, 1:6])</pre>
Cc <- covMcd (coleman.x) # truly robust</pre>
summary(Cc) # -> 6 outliers (1,3,10,12,17,18)
Cb1 <- mvBACON(coleman.x) ##-> subset is all TRUE hmm??
Cb2 <- mvBACON(coleman.x, init.sel = "dUniMedian")
stopifnot(all.equal(Cb1, Cb2))
## try 20 different random starts:
Cb.r <- lapply(1:20, function(i) { set.seed(i)
                    mvBACON(coleman.x, init.sel="random", verbose=FALSE) })
nm <- names(Cb.r[[1]]); nm <- nm[nm != "steps"]</pre>
all(eqC <- sapply(Cb.r[-1], function(CC) all.equal(CC[nm], Cb.r[[1]][nm]))) # TRUE</pre>
## --> BACON always breaks down, i.e., does not see the outliers here
## breaks down even when manually starting with all the non-outliers:
Cb.man <- mvBACON(coleman.x, init.sel = "manual",</pre>
                  man.sel = setdiff(1:20, c(1,3,10,12,17,18)))
which( ! Cb.man$subset) # the outliers according to mvBACON : _none_
```

Qrot

Rotation Matrix to Specific Direction

#### Description

Construct the  $p \times p$  rotation matrix that rotates the unit vector (1,0,...0), i.e., the  $x_1$ -axis, onto  $(1,1,1,...1)/\sqrt{p}$ , or more generally to u/||u|| (u :=unit.image).

#### Usage

Qrot(p, transpose = FALSE, unit.image = rep(1, p))

#### Arguments

р	integer; the dimension (of the vectors involved).
transpose	logical indicating if the <i>transposed</i> matrix is to returned.
unit.image	numeric vector of length $p$ onto which the unit vector should be rotated; defaults
	to "the diagonal" $\propto (1, 1, 1,, 1)$ .

#### Details

The qr decomposition is used for a Gram-Schmitt basis orthogonalization.

#### Value

 $p \times p$  orthogonal matrix which rotates (1, 0, ..., 0) onto a vector proportional to unit.image.

12

#### rbwheel

#### Author(s)

Martin Maechler

## See Also

qr, matrix (and vector) multiplication, %\*%.

## Examples

```
Q <- Qrot(6)
zapsmall(crossprod(Q)) # 6 x 6 unity <==> Q'Q = I <==> Q orthogonal
if(require("MASS")) {
    Qt <- Qrot(6, transpose = TRUE)
    stopifnot(all.equal(Qt, t(Q)))
    fractions(Qt ^2) # --> 1/6 1/30 etc, in an almost lower-triagonal matrix
}
```

```
rbwheel
```

Multivariate Barrow Wheel Distribution Random Vectors

#### Description

Generate *p*-dimensional random vectors according to Stahel's Barrow Wheel Distribution.

#### Usage

## Arguments

n	integer, specifying the sample size.
р	integer, specifying the dimension (aka number of variables).
frac	numeric, the proportion of outliers. The default, $1/p, {\rm corresponds}$ to the (asymptotic) breakdown point of M-estimators.
sig1	thickness of the "wheel", (= $\sigma$ (good[,1])), a non-negative numeric.
sig2	thickness of the "axis" (compared to 1).
rGood	function; the generator for "good" observations.
rOut	function, generating the outlier observations.
U1	p-vector to which $(1, 0, \ldots, 0)$ is rotated.

scaleAfter	logical indicating if the matrix is re-scaled <i>after</i> rotation (via scale()) Default TRUE; note that this used to be false by default in the first public version.
scaleBefore	logical indicating if the matrix is re-scaled before rotation (via scale()).
spherize	logical indicating if the matrix is to be "spherized", i.e., rotated and scaled to have empirical covariance $I_p$ . This means that the principal components are used (before rotation).
fullResult	logical indicating if in addition to the $n \times p$ matrix, some intermediate quantities are returned as well.

#### Details

••••

#### Value

By default (when fullResult is FALSE), an  $n \times p$  matrix of n sample vectors of the p dimensional barrow wheel distribution, with an attribute, n1 specifying the exact number of "good" observations,  $n1 \approx (1 - f) \cdot n$ , f = frac.

If fullResult is TRUE, a list with components

Х	the $n \times p$ matrix of above, X = X0 %*% A, where A <- Qrot(p, u = U1), and X0 is the corresponding matrix before rotation, see below.
XØ	
A	the $p \times p$ rotation matrix, see above.
n1	the number of "good" observations, see above.
n2	the number of "outlying" observations, $n2 = n - n1$ .

Recursive Robust Median-like Location and Scale

#### Description

Calculate an estimate of location, asymptotically equivalent to the median, and an estimate of scale equal to the **MEAN** absolute deviation. Both done recursively.

#### Usage

reclas(y, b = 0.2, mfn = function(n) 0.1 \* n^(-0.25), nstart = 30, m0 = median(y0), scon=NULL, updateScale = is.null(scon))

#### Arguments

У	numeric vector of i.i.d. data whose location and scale parameters are to be esti- mated.
b	numeric tuning parameter (default value equal to that used by Holst, 1987).
mfn	a function of the index of the data which must be positive and and tend to 0 as the index tends to infinity. The default function is that used by Holst, 1987.
nstart	number of starting values: Starting values for the algorithm are formed from the first nstart values of y. The default value is that used in Cameron and Turner, 1993.
mØ	value for the initial approximate median; by default, the median of the first nstart observations.
scon	value for the scale parameter s, a function or NULL. When NULL, as by default, the scale is initialized to the mean of the absolute differences between the first nstart y values and m0. If scon is a function, the initial scale is set to $scon(y0, m0)$ , where y0 is the vector of the first nstart y values. Note that scon also determines the default for updateScale.
updateScale	a logical indicating if the scale, initialized from scon should be updated in each iteration. Otherwise, the the scale is held constant throughout and the algorithm becomes equivalent to the algorithm of Holst.

## Value

An S3 "object" of class "reclas"; simply a list with entries

locn	the successive recursive estimates of location. The first ${\tt nstart}$ – 1 of these are NA.
scale	the successive recursive estimates of scale ${\bf if}$ updateScale is true; otherwise the constant value used for the scale.
updateScale	the same as the function argument.
call	the function call, i.e., match.call.

There is a plot method for "reclas", see the examples.

reclas

## Examples

```
set.seed(42)
y <- rt(10000, df = 1.5) # not quite Gaussian ...
z1 <- reclas(y)</pre>
z3 <- reclas(y, scon= 1 ) # correct fixed scale</pre>
z4 <- reclas(y, scon= 100) # wrong fixed scale
z2 <- reclas(y, # a more robust initial scale:</pre>
           scon = function(y0, m0) robustbase::Qn(y0 - m0),
           updateScale = TRUE) # still updated
## Visualizing -- using the plot() method for "reclas":
M <- median(y) ; yl <- c(-1,1)* 0.5
OP <- par(mfrow=c(2,2), mar=.1+c(3,3,1,1), mgp=c(1.5, .6, 0))</pre>
 plot(z1, M=M, ylim=yl)
 plot(z2, M=M, ylim=yl)
 plot(z3, M=M, ylim=yl)
 plot(z4, M=M, ylim=yl)
par(OP)
```
